An important branch of stereochemistry is the study of chiral molecules. Stereochemistry spans the entire spectrum of organic, inorganic, biological, physical and especially supramolecular chemistry. Stereochemistry includes methods for determining and describing these relationships; the effect on the physical or biological properties these relationships impart upon the molecules in question, and the manner in which these relationships influence the reactivity of the molecules in

Generally, within the scope of the sophomore organic chemistry course, we mention the stereoselectivity, but don't focus on it. Stereoselective reactions, such as Sharpless epoxidation, are incredibly important in organic synthesis. The stereoselective methods and the mechanisms of those reactions, however, are usually quite complex.

Stereochemistry is a branch of chemistry that involves the study of spatial arrangements of organic molecules and their manipulation. It involves the study of stereoisomers.

Stereoisomers are molecules having the same molecular formula and the atomic arrangement, but different spatial arrangements. The two main groups of stereoisomers are:
